

Semantic matching recovers the HRS-ELSA crosswalk without hand coding

Scored on 14 HRS items against all 403 ELSA derived variables, with the correct counterpart coded by hand from both codebooks; random guessing would score 0.2% at top-1. Panel A: top-k accuracy, where top-3 means the true match appeared among the three highest-scoring candidates. Panel B: a small margin means the matcher was nearly indifferent between its first and second choice, which is where a human should review. Panel C: true pairs score 0.55 on average against 0.03 for the 5,628 non-matching pairs. Fourteen items is a small answer key; these numbers show the approach is viable, not that it is validated at scale.
